EAS[®]-element clutch **EAS[®]-elements**

**Perfect overload protection
for high torques**

EAS[®]-element clutch/EAS[®]-element

Non-destructive Overload Protection

In heavy-duty machine building and on drives with high torques, high speeds and high mass moments of inertia, disengaging element clutches guarantee that the input and the output are separated completely in the event of a collision or a malfunction,

and that the stored rotational energy can slow down freely. In contrast to shear pins and hydraulic clamping sets, these clutches work in a non-destructive way and are therefore an interesting and economical alternative.

EAS[®]-elements

If the set circumferential force is exceeded in case of overload, the EAS[®]-elements disengage; the positive-locking connection is interrupted.

- ☐ Torque and force-limiting elements
- ☐ Residual torque-free separation of input and output in case of overload
- ☐ Mechanical re-engagement or re-engagement via pneumatic or hydraulic devices
- ☐ Fast and easy repeat operation start-up without using replacement parts
- ☐ Exact torque adjustment

EAS[®]-element clutch

The EAS[®]-element clutch is based on individual overload elements (EAS[®]-elements), which are integrated into hubs and flanges. Due to the modular structure, integration into existing constructions provided by the customer and ensuring of very high torques are possible.

- ☐ Torque limitation for heavy and high-speed drives in connection with large rotating masses, which have to slow down freely in case of overload
- ☐ Designs for direct attachment of drive elements
- ☐ Combinations with torsionally flexible couplings to connect two shafts and to compensate for shaft misalignments
- ☐ Extremely compact design as the perfect alternative to hydraulic clamping sets and shear pins

High Torque, Small Element - EAS[®]-element

Characteristics

- ☐ The torques on large clutches are limited
- ☐ Suitable for retrofitting into existing constructions
- ☐ Using EAS[®]-elements, customer-specific special requirements can be catered for

Application

- ☐ Also suitable for turntable and slew ring drives etc.
- ☐ Load securement, even in inclined or linear operation
- ☐ Even the largest torques are rendered manageable due to the application of as many EAS[®]-elements as necessary

Advantages/Benefits

- ☐ On overload, the entire system can be stopped by a speed monitor
- ☐ EAS[®]-elements allow a multitude of individual requirements
- ☐ The most cost-effective alternative in the field of large clutches
- ☐ Simple adjustment (force/torque)

*Rustproof design
available on request*

Functional Principle of the EAS[®]-element

- ☐ If the circumferential force per element is too large, the resulting axial force causes an axial movement of the bolt via the ball/calotte system and therefore disconnects the torque transmission.
- ☐ The maximum circumferential force is determined individually via the adjusting nut and the mayr[®]-cup springs. This limits the transmittable torque.
- ☐ Due to the axial stroke of the bolt (ball carrier), the control segments move radially outwards, thereby disconnecting the components axially.
- ☐ The ball is re-engaged via a bolt stroke in the direction of the calotte, either manually or via a mayr[®] re-engagement device.

EAS®-element

Fig. 1: EAS®-element engaged

Fig. 2: EAS®-element disengaged

Size Selection:

The limit torque for overload M_G on a clutch composed of elements can be calculated as follows:

$$M_G = z \times F_u \times r \quad [\text{kNm}]$$

M_G = Limit torque for overload in [kNm]

F_u = Circumferential force per element in [kN]
(see Dimensions Sheets)

r = Pitch circle radius onto which the elements are mounted in [m] (see Fig. 1)

z = Number of elements [-]

Fig. 3

The engagement procedure can be automated or operated by remote control when using mechanical, pneumatic or hydraulic aids.

Function:

EAS®-elements for installation in two bearing-supported flanges facing each other or for integration into existing constructions.

The EAS®-elements are available in 5 sizes (02 – 2).

In case of overload, the EAS®-elements separate the input and output mechanically, so that the system can slow down freely. Re-engagement of the individual elements is carried out by hand (automatic re-engagement available on request).

Torque Path:

Flange A (customer-side) – bolt 1 – balls 3 – thrust piece 2 – flange B (customer-side).

Processes for Torque Switch-off on Overload:

On overload, the two flanges A and B begin to turn against each other. Bolt 1 is pressed via the control segments 4 and the thrust washer 5 against the force of the cup springs 6 from the thrust pieces 2. The control segments 4 travel radially outwards over the bolt 1 switching edge and hold bolt 1 in a disengaged position (see Fig. 2). The positive-locking connection of the two clutch flanges A and B is nullified. The originally coupled masses can slow down freely. The drive is switched off electrically via speed monitoring device 13.

Design:

All element components consist of high-quality quenched and tempered steels with a zinc-phosphated surface which provides a basic corrosion protection for further surface treatments.

The bolt 1, the thrust pieces 2, the ball 3, the control segments 4 and the thrust washers 5 are hardened. The ball 3 is supported in bolt 1. It can be rotated and is secured against falling out.

The elements are also suitable for oil-running.

Re-engagement:

Re-engagement is carried out by applying axial pressure on the bolt end. The level of engagement force F_E is dependent on the set circumferential force F_u and can be roughly calculated using the following formula.

For element Type 440._04.0 $F_E = 0,12 \times F_u \text{ [kN]}$

For element Type 441.604.0 $F_E = 0,08 \times F_u \text{ [kN]}$

F_E = Engagement force per overload element in [kN]

F_u = Set circumferential force in [kN]

EAS®-element

Distance dim. a ₁	[mm]	1,0	1,5	2,0	2,0	3,0
Bolt pre-tension	[mm]	0,2	0,2	0,5	0,6	0,6

Table 1

Inspection Intervals:

For element Type 440_04.0: approx. 1 year or after every 1.000 disengagements.

For element Type 441.604.0: approx. 1 year or after every 100 disengagements.

Should the device be subject to very dirty, dusty or extreme ambient conditions, it may be necessary to carry out inspections at much shorter intervals. If the distance dimension a₁ increases substantially (see Table 2), the axial bearing of both clutch flanges must be checked.

EAS®-element		Size				
		02	01	0	1	2
Distance dimension a ₁ increase	[mm]	0,1	0,1	0,3	0,4	0,4

Table 2

Installation of the EAS®-elements, Sizes 02 – 2:

- ❑ The adaptor bores and the threaded holes for the EAS®-elements must be produced according to the Dimension Sheets or the Installation and Operational Instructions B.4.4.GB.
 - ❑ Before installation, please make sure that the elements are engaged. Measure the inspection dimension "p" according to the Table below. The elements are delivered in an engaged position ex works.
 - ❑ Install the EAS®-element into flange A. Please observe the tightening torque M_A according to the details in the Dimension Sheets.
 - ❑ Grease the thrust piece 2 (Fig. 4) or the adaptor bushing 14 (Fig. 5) well (Please use: grease NLGI class 2 with a basic oil viscosity of 220 mm²/s at 40 °C, e.g. Mobilgrease HP222) and insert in or screw onto flange B. The set screw 9 must be removed.
 - ❑ Screw-on the cover 10. The set screw 8 must be removed. Please observe the tightening torque M_A according to the details given in the Dimension Sheets.
 - ❑ Adjust the distance dimension a₁ according to Table 1 below.
 - ❑ Pre-tensioning the elements on Sizes 0 – 2:
Tighten the set screw 8. After adjustment, counter the set screw 8.
- For operation with impact and vibration occurrences it is recommended to carry out the bolt pre-tensioning alternatively by inserting shim rings.**
- Secure thrust piece 2 using set screw 9.
- Pre-tensioning the elements on Sizes 02 – 01:
Insert shim rings between the adaptor bushing and the thrust piece. (see Installation and Operational Instructions B.4.4.GB).
- ❑ Record the set distance dimension a₁ for subsequent inspections (the set distance dimension is calculated as follows: Distance dimension a₁ - bolt pre-tension).

Torque Adjustment:

The limit torque for overload on the clutch is adjusted by changing the cup spring pre-tension of each element. For Sizes 02 – 1, adjustment is carried out via the adjusting nut 7, for Size 2 via 4 set screws 11 (Fig. 4). All 4 set screws must be evenly adjusted and countered. During torque adjustment, it is essential that all elements on the clutch are adjusted evenly.

The EAS®-elements can be set to the required circumferential force F_U at the place of manufacture. Subsequent adjustment or re-adjustment via an adjustment diagram is also possible (see Installation and Operational Instructions B.4.4.GB).

Maintenance:

The EAS®-elements are completely enclosed and have a grease filling, meaning that they are mainly maintenance-free.

Maintenance work on the clutch is limited to the following:

- ❑ After the first 20 disengagements, check the clutch circumferential backlash and the originally set adjustment dimension "a₁"; if necessary, re-adjust the bolt pre-tension.
- ❑ Re-grease the contact components and thrust pieces (2).

For greasing, use an NLGI Class 2 grease with a basic oil viscosity of 220 mm²/s at 40°C, e.g. Mobilgrease HP222.

These inspections and re-greasing of the contact components and thrust pieces (2) are also necessary later during routine inspections.

The High-Torque-EAS[®]-element Clutch

Characteristics

- ☐ Designed for high torques
- ☐ As standard design up to 190.000 Nm
- ☐ Available with torque adjustment
- ☐ Individual constructional design according to the customer's requests
- ☐ In case of overload, the drive is switched off via a speed monitor
- ☐ Large and expensive heavy-duty machines are protected reliably against damage due to overload

Application

Used for example in:

- ☐ Shovel excavators
- ☐ Dredgers
- ☐ Turbine construction
- ☐ Water lock drives
- ☐ Rolling mills
- ☐ Steel plants

Advantages/Benefits

- ☐ Avoids downtimes
- ☐ Increases the availability
- ☐ Increases the production capacity

*Rustproof design
available on request*

Functional Principle of the EAS[®]-element clutch Overload elements

- ☐ If the proportional circumferential force on the individual elements proves too large, the resulting axial force causes an axial movement of the bolt via the ball/calotte system and therefore the disconnection of the torque transmission.
- ☐ The maximum circumferential force is individually determined through the adjusting nut and mayr[®]-cup springs. The transmittable torque is determined in this way.
- ☐ Due to the axial stroke of the bolt (ball carrier), the control segments move radially outwards and thus causes axial overload.
- ☐ Re-engagement of the balls through a bolt stroke in the direction of the calotte takes place either manually or via a mayr[®] re-engagement device (pneumatic, hydraulic, electromechanical or mechanical).

1) The values refer to 1500 rpm.

Technical Explanations

Fig. 1: EAS®-element clutch engaged

Fig. 2: EAS®-element clutch disengaged

$$F_E = k \times M_G \quad [\text{kN}]$$

F_E = Total engagement force for all clutch overload elements [kN] (see Fig. 3)

k = Calculation factor [1/m] acc. Table 1

M_G = Set limit torque for overload in [kNm]

		EAS®-Size									
		6	7	8	9	10	11	12	13	14	
Calculation factor k	[1/m]	1,7	1,4	1,3	1,0	0,8	0,6	0,5	0,4	0,3	

Table 1

Fig. 3

Design:

All element components are made of steel, are machined on all sides and have a zinc-phosphated surface which provides a basic corrosion protection for further surface treatments. The design of the installed EAS®-elements is as described on page 8. The clutch is also suitable for oil-running.

Torque Adjustment:

The limit torque for overload on the clutch can be adjusted by changing the cup spring pre-tension of each overload element. For Sizes 6 – 11, adjustment is carried out via the adjusting nut 3.7, for Sizes 12 – 14 via set screws 3.11 (see Fig. 1). It is essential that all overload elements on the clutch are adjusted evenly. The EAS®-element clutches Sizes 6 – 14 can be set to the required limit torque for overload at the place of manufacture. Subsequent adjustment or re-adjustment via an adjustment diagram is also possible (see Installation and Operational Instructions B.4.3.EN).

Torque Path:

Hub part 1 – bolt 3.1 – balls 3.3 – thrust piece 3.2 – output flange 2

Processes for Torque Switch-off on Overload:

On overload, the hub part 1 and the output flange 2 begin to turn against each other. The bolts 3.1 in the overload elements are pressed via the control segments 3.4 against the force of the cup springs 3.6 from the thrust washers 3.2. The control segments 3.4 travel radially outwards over the bolt 3.1 switching edge and hold the bolts 3.1 in a disengaged position (see Fig. 2). The positive-locking connection of the hub part 1 and the output flange 2 is nullified. The originally coupled masses can slow down freely. The drive is switched off electrically via speed monitoring device 4.

Re-engagement:

Re-engagement is carried out by applying axial pressure on the bolt end 3.1 of each overload element. The hub part 1 and the output flange 2 are turned into the correct angular position to one another (re-engagement position can be recognized via the marking bores on the clutch outer diameter, Fig. 2). By hitting the bolt end with a plastic hammer, the bolts 3.1 are brought back into an engaged position. The clutch is ready for operation when all clutch overload elements are engaged. The level of engagement force is dependent on the set limit torque for overload and can be calculated roughly using the formula below.

Re-engagement can also be carried out automatically using compressed air. If you are interested in this feature, please contact the manufacturer.

Mounting onto the Shaft:

In a standard delivery, the EAS®-element clutches Sizes 6 – 14 are delivered with a finish bore and a keyway acc. DIN 6885. The clutch can be secured axially onto the shaft e.g. using a washer and a screw, screwed into the shaft threaded centre hole.

Other shaft-hub connections, e.g. multi-splines, toothings, shrink fits, pressurised oil assemblies etc. are also possible.

Technical Explanations

Fig. 1

Installation Example

Fig. 2

Dimensioning the Flexible Coupling Part Type 435._04.5

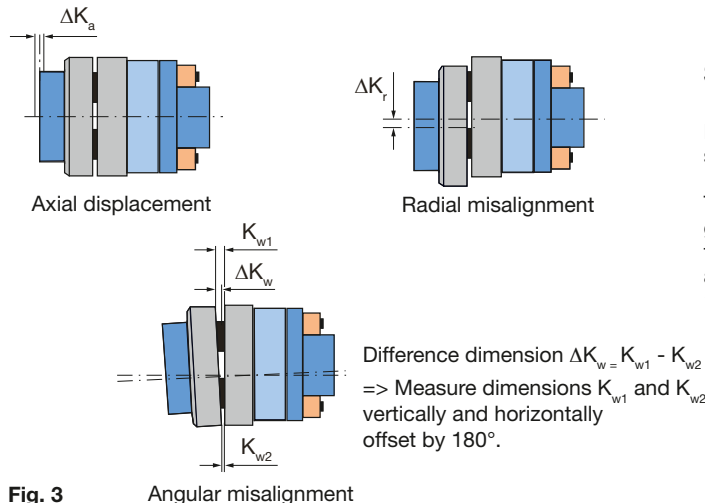

Fig. 3

Maintenance

The EAS®-element clutches Sizes 6 – 14 do not require special maintenance work. They are largely protected against dust and humidity, they have an initial grease filling and are therefore mainly maintenance-free.

The distance dimension a_1 between the thrust piece and the overload element facing side is set manufacturer-side and does not require any re-adjustment (Fig. 1).

Special maintenance work may be necessary, however, if the device is subject to large amounts of dirt or dust or is operating in extreme ambient conditions.

In this case, please contact the manufacturer.

Connecting the drive elements as shown in Fig. 2 means better distribution of the radial and axial forces on the bearing. In this case, the resulting radial force of the drive element lies approximately in the bearing centre.

For this design, please contact the manufacturer.

Shaft Misalignments

Flexible coupling for the compensation of axial, radial and angular shaft misalignments.

The misalignment possibilities of the flexible coupling are general guideline values, which can be regarded as adequate with regard to producing the required longest possible clutch service lifetime and bearing support for the shafts (see Table "Technical Data", page 15).

Fig. 4

If more than one kind of misalignment occur simultaneously, they influence each other. The permitted misalignment values are dependent on one another, see Fig. 4. The sum total of the misalignments – in percent of the maximum value – must not exceed 100 %.

Example:

EAS®-element clutch, Size 6, Type 435.604.5

- ☐ **Axial displacement** occurrence:
 $\Delta K_a = 0,4 \text{ mm}$, equals **20 %** of the permitted maximum value $\Delta K_a = 2 \text{ mm}$
- ☐ **Angular misalignment** occurrence:
 $\Delta K_w = 0,09 \text{ mm}$, equals **30 %** of the permitted maximum value $\Delta K_w = 0,3 \text{ mm}$
- ☐ Required **permitted radial misalignment**:
 $\Delta K_r = 50 \%$ of the permitted maximum value $\Delta K_r = 0,3 \text{ mm}$ equals $\Delta K_r = 0,15 \text{ mm}$

Technical Explanations

Dimensioning the Flexible Coupling Part Type 435._04.5

1. Approximate Calculation of the Coupling Torque

The nominal torque T_N and the maximum torque T_{max} from the basis of the flexible coupling dimensioning.

$$T_N = \frac{9550 \times P_N}{n}$$

2. If Nominal Torque is Applied, the Following Applies:

$$T_{KN} > T_N \times S_\theta \times S_f$$

3. Checking the Coupling Maximum Torque:

For short torque impacts, which occur for example when starting an electromotor, the following applies:

$$T_{Kmax} > T_{max} \times S_\theta \times S_z$$

Terms

P_N	[kW]	System performance	
T_N	[Nm]	System torque	
T_{KN}	[Nm]	Coupling torque	see page 15
T_{Kmax}	[Nm]	Maximum coupling torque	see page 15
T_{max}	[Nm]	Maximum torque impact of the system	
n_N	[rpm]	Operating speed	
S_A	[-]	Load factor, input-side	see Table
S_L	[-]	Load factor, output-side	see Table
S_f	[-]	Service factor	$= S_A \times S_L$
S_z	[-]	Start-up factor	see Table
S_θ	[-]	Temperature factor	see Table

S_L = Load Factor, Output-side		
Torque characteristics at the operating point, input-side	Minimum load factor $[S_L]$	
Consistent, even without torque fluctuations		1
Even, with minor fluctuations, light impacts		1,25
Uneven, also API-671, API-610, moderate impacts		1,5
Uneven, fluctuating, strong impacts		1,75
Other torque characteristics	Own data/torsional vibration calculation	

S_θ = Temperature Factor, Depending on the Intermediate Ring Material Pb 72, Pb 82 (NBR)	
Ambient temperature range [°C]	Temperature factor for intermediate ring quality $[S_\theta]$
-30/ +60	1
+80	1,2
+100	1,3
> +100	On request

S_A = Load Factor, Input-side	
Driven by	Minimum load factor $[S_A]$
E-motor, turbine	1
Hydraulics motor	1,1
Internal combustion engine, 4 or more cylinders, U-degree $\leq 1 : 100$	1,2 (TVC) ¹⁾
Internal combustion engine, 1 or 3 cylinders, U-degree $\geq 1 : 100$	1,4 (TVC) ¹⁾

S_z = Start-up Factor	
Start-up frequency [1/h]	Start-up factor $[S_z]$
< 120	1
120 - 240	1,3
> 240	On request

1) We recommend carrying out a torsional vibration calculation (TVC) for coupling dimensioning on drives with internal combustion engines.

Special Designs

Apart from our established EAS®-element clutch designs, we also offer specially constructed variants according to customer request. EAS®-element clutches can be combined with many different components, for example flexible couplings, gear coupling etc.

We are happy to assist you in dimensioning and assembling your optimum design.

Example 1: EAS®-element clutch

with cardan shaft connection and stable bearing for absorbing large forces

Technical Data
